|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <p>Write a C++ program to create a class called STACK using an array of integers (memory should be dynamically allocated for array for the user requested size) and implement the following operations by overloading the operators +, ++ and -- :</p> <ul style="list-style-type: none">i. $s1 = \text{element} + s1$; where $s1$ is an object of the class STACK and element is an integer to be pushed on to top of the stack.ii. $s1 = s1 - -$; where $s1$ is an object of the class STACK and -- operator pops off the top element.iii. $s1 = s1 ++$; where $s1$ is an object of the class STACK and ++ operator should increment the value of each element in the stack by 1. <p>You have to handle the STACK Empty and STACK Full conditions. Also display the contents of the stack after each operation, by overloading <<.</p> |
| 2 | <p>Write a JAVA program to add two integers using command line arguments.</p> |
| 3 | <p>Write a C++ Program to create a class called LIST (linked list) with the following member functions.</p> <ul style="list-style-type: none">$L = L + \text{ele}$; will add ele to all the elements in the list that are less than ele.$L = L - \text{ele}$; Search a node with an element ele in the list L and remove the node with ele from L.$L3 = L1 == L2$; should join L1 to L2 if lists L1 and L2 are same with respect to elements and store the new list in L3.$L1 = L1 ++$; should convert the negative values (if any) in the list into their positive and sort the list. <p>Overload << to display the content of the list after every list operations. In addition to the above functions you can add your own functions if needed.</p> |
